The Lapita-associated Human Material from Lakeba, Fiji

PHILIP HOUGHTON
Department of Anatomy, University of Otago
P.O. Box 913, Dunedin, New Zealand

ABSTRACT. The remains of an individual interred about the middle of the first millenium BC, in association with Lapita ceramics, on the island of Lakeba in the Lau group of Fiji, have been examined. The long bones were robust and showed marked bowing and other evidence of considerable muscularity. The femur had an oval fovea and marked platymeria (index 71). Stature was estimated at 1,715 mm. The incomplete jaw was of 'rocker' form on one side and showed a very slight antegonial notch on the other. The morphology of this individual is fully compatible with the known Polynesian skeletal phenotype.

Material

The remains were of an adult male, probably in the fourth decade of life (30 to 40 years). The long bones were robust (though a defined robusticity index was not obtainable) and with physiologically bowed shafts to accommodate a considerable musculature. The maximum length of the intact right radius was 245 mm, and of the right ulna 266 mm. Derived stature estimates using different equations are given in Table 1. The Polynesian equations of Houghton et al. (1975) gave the mid-estimates and also the least range; a stature of 1,715 mm is suggested. The upper femoral shafts were markedly flattened with a platymeric index of 71, rather greater than that found in the prehistoric Maori (Schofield, 1959) but similar to prehistoric Hawaii (Snow, 1974). The femoral heads showed distinct oval foveae (Fig.2). The forearm bones showed the marked bowing characteristic of Polynesians and the humeri showed prominent deltoid tuberosities. The spine was represented by several vertebrae from neck to lumbar region. The cervical and lumbar vertebrae were intact. The left upper limb bones are slightly more robust than the left and this individual was thus presumably right-handed.

The cranial fragments offered little information, but the mandibular body and about half of each ramus were present. This bone was not particularly robust, though function would have been influenced by extensive dental caries in both jaws. The mandible verged on the rocker form, the right side displaying no antegonial notch and
