Abstract. Descriptions of six new species of Australian jawfishes (genus *Opistognathus*) are presented: *O. alleni* n.sp. (Western Australia), *O. seminudus* n.sp. (Great Barrier Reef), *O. stigmosus* n.sp. (Great Barrier Reef and Coral Sea Plateau), *O. elizabethensis* n.sp. (Tasman Sea, Elizabeth Reef), *O. verecundus* n.sp. (northern Australia), and *O. reticeps* n.sp. (northern Australia). The nominal genus *Tandya* Whitley is discussed and provisionally synonymized with *Opistognathus* Cuvier. An identification key to all Australian jawfishes is provided.

Opistognathus alleni n.sp.

Figs. 1, 2A, 3A, 4A; Tables 1–4

Opistognathus sp.—Allen & Swainston, 1988:126, pl. 54, colour fig. 814 (brief diagnosis; common name “Abrolhos jawfish”).

Type material. HOLOTYPE: WAM P.27590-030, male (73.7), Western Australia, Houtman Abrolhos Archipelago, N. end of Dicks Island, in Goss Passage, 28°30’S 113°46’E, 30–32 m, G.R. Allen and N. Sinclair, 17 Apr. 1982.

PARATYPES: 39 specimens, 45.4–72.4 mm, all from Western Australia. WAM P.27590-002 (11, 47.4–72.4), same data as holotype; WAM P.27587-003 (54.0), Houtman Abrolhos Archipelago, S. end Long Island, in Goss Passage, 28°29’S 113°46’E, 25–32 m, G.R. Allen, 16 Apr. 1982; AMS I.33668-001 (3, 51.4–66.1), ANSP 157594 (4, 53.8–66.2), 1 C&S, NTM S.13294-001 (3, 50.5–55.1), USNM 315663 (3, 62.7–68.7) and WAM P.27595-003 (9, 45.4–51.2), Houtman Abrolhos Archipelago, all from Long Island, in Goss Passage, 30–33 m, G.R. Allen et al., 19 Apr. 1982.

MPM 33192 (53.7), Exmouth Gulf, Burnside Island, 22°5’33”S 114°30’55”E, 0–0.6 m, R.D. Mooi, A.C. Gill, J.B. Hutchins and R.C. Miles, 19 May 1996. BMNH 2001.11.28.1 (45.3) and MPM 33191 (2, 40.6–46.8), Locker Island, 21°42’12”S 114°45’48”E, 0–0.2 m, R.D. Mooi, A.C. Gill and R.C. Miles, 16 May 1996. MPM 33190 (45.9), Bessieres Island, 21°31’2”S 114°45’13”E, 13–15 m, R.D. Mooi, A.C. Gill, R.C. Miles and N. Williams, 15 May 1996.

Diagnosis. A species of *Opistognathus* with dorsal fin X, 19 (rarely 20); body with about 21–31 oblique scale rows in longitudinal series, and scales absent anterolaterally forward of verticals from 6th to 9th segmented dorsal-fin rays; spinous dorsal fin with a broad dark submarginal stripe and spine tips with pale fleshy tabs; vomerine teeth 1–3.

Scales absent on body anterolaterally forward of verticals from 6th to 9th segmented dorsal-fin rays, and from head, nape, area above lateral line, pectoral-fin base and breast; belly squamation varying from completely naked to posterior ¼ scaly. Body with about 21–31 oblique scale rows in longitudinal series. Lateral-line terminus below verticals from 13th to 17th segmented dorsal-fin rays (total element position 23–27). Lateral line pores numerous, arranged in multiple series above and below embedded lateral-line tubes. Cephalic sensory pores very numerous, in adults completely covering most of head, including all of predorsal area except a small area immediately adjacent

Fig. 1. *Opistognathus alleni*, paratype, WAM P.27590-002, female, 72.4 mm SL, Houtman Abrolhos Archipelago, Western Australia. Drawn by Jack R. Schroeder.

Fig. 2. Maxilla and supramaxilla (shaded): A, *Opistognathus alleni*; B, *O. seminudus*; C, *O. verecundus*; D, *O. reticeps*. Data as in figure 3; scale bars represent 2 mm.
very slender and Y-shaped (Fig. 4A). with a slight suborbital shelf. Second pharyngobranchial sensory canals (Fig. 3A); 3rd infraorbital relatively robust. 1–3. Infraorbital bones tubular with wide openings for those in innermost row canted backwards. V omerine teeth (about same size as anterior, outer row teeth) anteriorly, usually slightly larger midlaterally, and 3 or 4 inner rows of backwards. Dentary with outer row of conical teeth (slightly symmetrically). Premaxilla with a single row of canted backwards. Jaw formation of maxilla and mouth pale or light brown but without bands below or slightly behind posterior margin of eye; inner orbital rim, at least dorsally; upper lip with 1 or 2 dusky dark margin; in large specimens, dusky spots usually ring specimen); posterodorsal margin of opercular flap with base with large white spot (not shown in illustrated specimen); preopercle straight and slightly rounded posterodorsally; posterior margin of preopercle indistinct, without a free margin. No papillae on inner surface of lips. Fifth cranial nerve passes under A1β section of adductor mandibulae.

Upper jaw not sexually dimorphic, extending 0.4 to 0.6 eye diameters behind posterior margin of orbit; maxilla widest at end and truncate, without flexible lamina posteriorly (Fig. 2A); supramaxilla present, small and terminally positioned. Jaws subequal. Premaxilla with an outer row of moderate conical teeth that become progressively smaller and more closely spaced posteriorly and extend ½ length of jaw; 1 or 2 rows of smaller inner teeth anteriorly, and usually 2–3 inner teeth on each side of premaxillary symphysis that are somewhat enlarged and canted backwards. Dentary with outer row of conical teeth (slightly smaller than outer symphyseal premaxillary teeth) that are usually slightly larger midlaterally, and 3 or 4 inner rows of teeth (about same size as anterior, outer row teeth) anteriorly, those in innermost row canted backwards, Vomerine teeth 1–3. Infraorbital bones tubular with wide openings for sensory canals (Fig. 3A); 3rd infraorbital relatively robust with a slight suborbital shelf. Second pharyngobranchial very slender and Y-shaped (Fig. 4A).

to dorsal-fin origin; mandibular pore positions 1–3 occupied by relatively large, single pores, 4th position with 6–12 pores, 5th position with 19–30.

Anterior nostril distinctly closer to posterior nostril than to dorsal margin of upper lip, and with a simple, flattened tentacle on posterior rim that when depressed reaches margin. No papillae on inner surface of lips. Fifth cranial nerve passes under A1β section of adductor mandibulae.

Measurements of the 73.7 mm holotype (in parentheses) and 12 paratypes, 54.3–72.4 mm, as percentage of SL: predorsal length (31.2) 28.1–31.8; preanal length (53.4) 53.8–59.0; dorsal-fin base (71.2) 69.4–73.9; anal-fin base (40.2) 37.6–43.0; pelvic-fin length (18.0) 17.0–20.4; caudal-fin length (19.5) 17.9–20.8; depth at anal-fin origin (14.2) 12.0–15.6; head length (31.3) 28.7–33.0; orbit diameter (9.2) 8.3–10.4; upper jaw length (15.0) 14.2–16.3. As percentage of head length: postorbital head length (64.9) 63.6–68.4; upper jaw length (47.9) 46.8–52.0; postorbital jaw length (16.3) 15.9–17.7; total dorsal-fin elements 94.6–111.4.

Preserved coloration. Head and body with scattered pale spots and mottled with various shades of brown; sides with dark middorsal stripe about width of eye and bordered above and below by a row of pale spots, some poorly defined, that contact margins of stripe giving it a scalloped outline; dorsum of some specimens with about 8–10 evenly spaced tan blotches superimposed with small dark spots that extend slightly below lateral line along dorsal-fin base and alternate with upper row of pale spots; pectoral-fin base with large white spot (not shown in illustrated specimen); postorbital dorsal margin of opercular flap with dark margin; in large specimens, dusky spots usually ring orbital rim, at least dorsally; upper lip with 1 or 2 dusky bands below or slightly behind posterior margin of eye; inner lining of maxilla and mouth pale or light brown but without a distinct blotch or stripe; spinous dorsal fin with a broad submarginal brown stripe and spine tips with noticeably pale fleshy tabs; soft dorsal fin with a narrow dark stripe near base of fin that is bordered above by several rows of small dark spots or blotches; anal fin mostly pale, usually with very narrow brown stripe on proximal third of fin; caudal fin with a pair of pale, oblong, basicaudal spots widely separated by a brown blotch that is a continuation of the middorsal stripe; otherwise caudal fin mostly pale with very faint dusky bands or spots that are best developed on dorsal half of fin; pelvic and pectoral fins immaculate. Some of the non-Houtman Abrolhos Archipelago paratypes (which appear to have better preserved colour patterns) have
a conspicuous white cheek spot, positioned slightly below the mid-point of postorbital margin of eye that is bordered above by a small dark spot, and 1 or 2 white spots on the opercle.

**Live coloration** (based on photograph, taken by R.D. Mooi, of freshly collected 53.7 mm SL specimen from Burnside Is.): dark chocolate brown stripe in dorsal and anal fins and midlaterally on sides; background coloration of head and body light yellowish brown; pale spots on cheek, opercle, pectoral-fin base and most of those below midlateral stripe on sides white, other pale spots light yellowish brown; iris pale yellow with a few narrow dark bands radiating from pupil. This individual also has small prominent white spots on the belly that are either absent or less defined in the other specimens.

**Etymology.** Named in honour of Dr Gerald R. Allen, who recognized the undescribed status of this species, generously made his material available for this study, and whose publications have contributed significantly to knowledge of Indo-Pacific fishes.

**Distribution.** Known only from Western Australia in depths of 0.2–33 m.

**Remarks.** In *O. alleni* the second pharyngobranchial is very slender and essentially Y-shaped (Fig. 4A), in most other species of *Opistognathus* this edentate bone is rod-like with the distal end slightly to moderately expanded (character not examined in *O. stigmosus* and *O. elizabethensis*), and in *O. seminudus* the end is greatly expanded (Fig. 4B).
Opistognathus seminudus n.sp.
Figs. 2B, 3B, 4B, 5, 6; Tables 1–4

Opistognathus sp.—Russell, 1983:107 (listed; Heron and One Tree islands).

**Type material.** HOLOTYPE: AMS I.22794-001, female (59.7), Australia, Great Barrier Reef, Capricorn Group, One Tree Island, reef flat at SW end of island, 0–1 m, V.G. Springer, 30 Nov. 1966, Sta. 66–13. PARATYPES: 78 specimens, 17.7–86.2 mm, all from the Great Barrier Reef. Capricorn Group, One Tree Island: ANSP 142950 (8, 21.5–73.7, 3 C&S) and USNM 220928 (14, 59.5–3.7), same data as holotype; AMS I.15641-042 (73.2), AMS I.15681-063 (4, 60.7–76.1), AMS I.17445-031 (9, 73.0–47.3), 3 m, F. Springer, 27 Nov. 1966; and USNM 295803 (3, 80.3–86.2), 4.5 m, V.G. Springer, 11 Dec. 1966. Capricorn Group, Wistari Reef: BPBM 14535 (54.0), 22 m, J.E. Randall, 22 Jan. 1973. Capricorn Group, Heron Island: AMS IB.4054–5 (2, 59.8–64.9), AMS I.15482-002 (48.6), H. Choat, 16 Jun. 1965; and USNM 295804 (64.9), H. Choat, 23 Feb. 1967. Gillett Cay: AMS IB.6126 (71.9), and AMS IB.6128 (3, 49.8–54.7), Swains Reef Expedition, Oct. 1962. Lizard Island: AMS I.20766-010 (2, 54.5–57.7), D. Hoese et al., 6 Feb. 1975.

**Diagnosis.** A species of Opistognathus with dorsal fin XI (exceptionally X), 14–16; body with about 28–36 oblique scale rows in longitudinal series, and with scales absent anterolaterally forward of verticals from ultimate spine to 2nd segmented dorsal-fin ray; dorsal fin with conspicuous ocellus between spines 2–5; vomerine teeth 1–3.

Scales absent on body anterolaterally forward of verticals from ultimate spine to 2nd segmented dorsal-fin ray, and from head, above lateral line, pectoral-fin base, breast and belly. Body with about 28–36 oblique scale rows in longitudinal series. Lateral-line terminus below verticals from 7th to 11th segmented dorsal-fin rays (total element position 18–22). Lateral line pores numerous, arranged in multiple series along embedded lateral-line tubes. Cephalic sensory pores very numerous (Fig. 6), in adults completely covering most of head, including all of preoral area except a small area immediately adjacent to dorsal-fin origin; mandibular pore positions 1–3 occupied by relatively large, single pores, 4th position with 4–10 pores, 5th position with 12–24.

Anterior nostril distinctly closer to posterior nostril than to dorsal margin of upper lip, and with a simple, flattened tentacle on posterior rim that when depressed usually reaches margin of orbit; height of tentacle about 1.5 to 2.0 times maximum diameter of posterior nostril. Dorsal fin very low anteriorly, gradually increasing in height posteriorly; profile relatively uniform with only a slight change in fin height at junction of last spine and anterior segmented rays. Dorsal-fin spines relatively short and straight, at most only slightly curved distally and without flexible tips; tips of spines with slightly swollen fleshy tabs; all segmented dorsal- and anal-fin rays branched distally or 1st anal ray unbranched. Outermost segmented pelvic-fin ray not tightly bound to adjacent ray, interradial membrane incised distally. Upper margin of opercle straight and slightly rounded posterodorsally; posterior margin of preopercle indistinct without a free margin. No papillae on inner surface of lips. Fifth cranial nerve passes under A1β section of adductor mandibulae.
Upper jaw slightly sexually dimorphic, extending 0.8 to 1.1 (♂) and 0.6–0.9 (♀) eye diameters behind posterior margin of orbit; maxilla widest at end and rounded, without flexible lamina posteriorly (Fig. 2B); supramaxilla present, small and terminally positioned. Jaws subequal. Premaxilla with an outer row of stout conical teeth that become progressively smaller posteriorly; 1 or 2 inner rows of smaller conical teeth anteriorly, those nearest symphysis largest and usually canted backward. Dentary with an outer row of moderate teeth, largest midlaterally, extending ½ to ¾ length of jaw, and an inner row of smaller conical teeth anteriorly that are usually strongly hooked backward. Vomerine teeth 1–3. Infracapsular bones tubular, with wide openings for sensory canals (Fig. 3B); 3rd infracapsular relatively robust and “L” shaped with a slight suborbital shelf. Second pharyngobranchial rod-shaped with distal end greatly expanded (Fig. 4B).

Measurements of the 59.7 mm female holotype (in parentheses) and 23 paratypes, 13 ♂ 57.9–86.2 mm and 10 ♀ 60.6–73.7 mm, as percentage of SL: predorsal length (30.9) 29.9–35.0; preanal length (58.6) 58.8–64.7; dorsal-fin base (67.0) 62.9–70.1; anal-fin base (31.6) 29.4–35.4; pelvic-fin length (24.6) 17.3–25.2; caudal-fin length (22.5) 21.4–24.8; depth at anal-fin origin (16.9) 14.9–19.1; head length (34.0) 33.0–36.2; orbit diameter (11.5) 9.9–11.5; upper jaw length (19.4) 19.9–22.3 ♂, 18.8–22.1 ♀. As percentage of head length: postorbital head length (63.6) 62.6–69.0; upper jaw length (57.1) 56.8–64.0 ♂, 55.1–64.2 ♀; postorbital jaw length (24.4) 23.4–32.5 ♂, 19.5–25.7 ♀; orbit diameter (34.0) 27.5–33.6.

Preserved coloration. Head and body various shades of brown; several irregular, wavy rows of pale marking or oblong spots on body and a wedge-shaped basicaudal blotch extending onto middle caudal-fin rays; larger specimens with many tiny black spots scattered on head and jaws; branchiostegal membranes and inner lining of maxilla and adjacent membranes dark brown, and a dark diagonal blotch externally on upper jaw positioned at rictus of mouth; dorsal fin mostly pale except conspicuous ocellus between spines 2–5 and a narrow dark stripe immediately behind ocellus (only a continuous dark stripe in small juveniles) extending length of fin diagonally to just above base of last ray; dorsal-fin spines with distinctly pale slightly fleshy tabs; anal fin pale with a narrow, suprabasal, dark stripe; pelvic, pectoral, and caudal fins immaculate.

Live coloration (based on aquarium photograph taken by P.C. Heemstra, of a 79.4 mm SL specimen from Heron Is.): pale background coloration of head and body mostly white, as are pale areas in fins; spot in ocellus black and other dark areas various shades of brown.

Etymology. The specific epithet, from the Latin semi (half) and nudus (bare, naked), refers to the naked anterior half of the body.

Distribution. Endemic to the Great Barrier Reef where collected in 0.5–22 m.

Diagnosis. A species of Opistognathus with dorsal fin X, 19; body with about 38–45 oblique scale rows in longitudinal series, and with scales absent anterolaterally forward of verticals from 5th to 7th dorsal-fin spines; lower half of sides with longitudinal row of 7 or 8 large white spots, the largest with a dark brown border and covered by appressed pectoral fin; vomerine teeth absent.

Scales absent on body anterolaterally forward of verticals from 5th to 7th dorsal-fin spines; lower half of sides with longitudinal row of 7 or 8 large white spots, the largest with a dark brown border and covered by appressed pectoral fin; vomerine teeth absent.

Measurements of the 70.5 mm holotype (in parentheses) and 3 paratypes, 42.9–62.5 mm. as percentage of SL: predorsal length (55.2) 32.8–35.0; preanal length (54.9) 55.6–58.6; dorsal-fin base (69.1) 67.4–71.8; anal-fin base (34.5) 36.3–36.7; pelvic-fin length (23.0) 23.0–23.6; caudal-fin length (19.4) 19.4–22.3; depth at anal-fin origin (15.6) 13.9–16.3; head length (34.5) 33.5–35.0; orbit diameter (11.5) 11.5–12.1; upper jaw length (19.3) 17.3–19.0. As percentage of head length: postorbital head length (61.2) 59.3–61.7; upper jaw length (55.9) 51.5–54.3; postorbital jaw length (15.2) 12.8–14.0; orbit diameter (33.3) 34.2–34.7.

**Preserved coloration.** Head and body overall tan, longitudinal row of 7 or 8 large white spots on lower half of sides; the largest with a dark brown border, widest ventrally, and covered by appressed pectoral fin; a second row of smaller indistinct pale spots above primary row; laterally a small dark spot present opposite dorsal ½ of otherwise pale pectoral-fin base; this spot on mesial side of pectoral-fin base where it may continue downward as a diagonal mark; small dark blotch also present on body immediately above pectoral-fin base; head and sides punctuated with widely scattered small dark brown spots, including one just behind postero dorsal margin of upper jaw; other dark spots ring orbital rim, those in interorbital region always very dark and symmetrically arranged in bilateral pairs; conspicuous dark spots or bands on upper and lower lips, two largest specimens each with 6 bands on lower lip; inner lining of maxilla and mouth immaculate; spinous dorsal fin with submarginal narrow dark stripe; tips of dorsal-fin spines with noticeably pale fleshy tabs; soft dorsal and anal fins with narrow dark suprabasal stripe bordered above by diffuse submarginal brown stripe, and dark bands or spots; caudal fin with pair of pale basicaudal spots (separated by a narrow inverted wedge-shaped blotch with a pale centre) followed by 1 or 2 dusky bands separated by pale interspaces; pelvic and pectoral fins immaculate.

**Live coloration** (based on Randall *et al.*, 1990): body and head various shades of brown, pale spots and markings white; iris yellow with a few narrow dark bands radiating from pupil.

**Etymology.** The specific epithet, from the Latin *stigmosus* (full of marks), refers to the conspicuous, small dark spots on the head of this species.

**Distribution.** Known only from the Great Barrier Reef (Escape Reef) and the Coral Sea Plateau (Lihou Reef) in 20–29 m.

**Opistognathus elizabethensis** n.sp.

Figs. 3D, 8; Tables 1–4

“*Opistognathus* n.sp.”—Gill & Reader. 1992:220 (listed in an annotated checklist of fishes collected at Middleton and Elizabeth Reefs).

**Type material.** HOLOTYPE: AMS L.27891–010, male (60.4), Elizabeth Reef, N side near lagoon entrance, 29°56′S, 159°01′E, 0–5 m, explosives, D.M. Williams, *et al.*, Dec. 1981. PARATYPES: 3 specimens, 66.6–71.4 mm. AMS L.27891–048, gravid females (2, 66.6–70.8), same data as holotype; AMS L.27152–014, male (71.4), Elizabeth Reef, outer SW reef slope, 29°57′S, 15°02′E, 15–18 m, A. Gill and S. Reader, 10 Dec. 1987.

**Diagnosis.** A species of *Opistognathus* with dorsal fin XI, 18 or 19; body with about 47–51 oblique scale rows in longitudinal series, and scales absent anterolaterally forward of verticals from 6th or 7th dorsal-fin spine; dorsal fin with an oblong black spot (partially encircled by white border) between spines 3–6 that extends slightly onto dorsum; vomerine teeth 2 or 3.

Scales absent on body anterolaterally forward of verticals from 6th or 7th dorsal-fin spine, and from head, nape, and slightly below lateral line, pectoral-fin base, breast and anterior ½ of belly. Body with about 47–51 oblique scale rows in longitudinal series. Lateral-line terminus below verticals from 4th to 7th segmented dorsal-fin ray (total...
Table 4. Frequency distributions of lateral-line terminus in relation to total dorsal-fin element position in selected Australian species of Opistognathus (holotype values in boldface). When terminus ended mid-way between two elements, the higher number was used.

Fig. 8. *Opistognathus elizabethensis*, holotype, AMS I.27891-010, male, 60.4 mm SL, Elizabeth Reef. Drawn by Tracy D. Pedersen.

Element position 15–18. Lateral line pores moderate, arranged in single series above and below embedded lateral-line tubes. Cephalic sensory pores numerous, completely covering most of head, including all of predorsal area except a small area immediately adjacent to dorsal-fin origin; mandibular pore positions 1–3 occupied by relatively large, single pores, 4th position occupied by 1–3 pores, 5th position with 7–11 pores.

Anterior nostril about midway between posterior nostril and dorsal margin of upper lip, consisting of a raised tube with a short tentacle on posterior rim that when depressed does not reach or barely reaches margin of posterior nostril; height of tentacle about 0.5 to 1.0 times maximum diameter of posterior nostril. Dorsal fin moderately low anteriorly, gradually increasing in height posteriorly; profile relatively uniform with only a slight change in fin height at junction of spinous and segmented rays. Dorsal-fin spines moderately short and straight, not curved distally and without flexible tips; skin covering tips of spines with slightly swollen fleshy tabs; all segmented dorsal- and anal-fin rays branched distally. Outermost segmented pelvic-fin ray not tightly bound to adjacent ray, interradial membrane incised distally. Upper margin of opercle straight and slightly rounded posterodorsally; posterior margin of preopercle indistinct without a free margin. No papillae on inner surface of lips. Fifth cranial nerve passes under A1β section of adductor mandibulæ.

Upper jaw not sexually dimorphic, extending 0.6 to 0.9 eye diameters behind posterior margin of orbit; maxilla widest at end and truncate, without flexible lamina posteriorly; supramaxilla small and terminally positioned. Jaws subequal, lower slightly included. Premaxilla with moderate conical teeth in lower row that become progressively smaller and more closely spaced posteriorly; 1 or 2 rows of much smaller inner teeth anteriorly, and 2 or 3 inner teeth on each side of premaxillary symphysis that are as large or larger than outer teeth and hooked backwards. Dentary with outer row of conical teeth (slightly smaller than outer, anterior premaxillary teeth) that are largest midlaterally; 2 inner rows of teeth (about same size as anterior outer row teeth) anteriorly, with most teeth in innermost row slightly canted backwards. Vomerine teeth 2 or 3. Infraorbital bones tubular, with wide openings for sensory canals (Fig. 3D); 3rd infraorbital relatively robust and “L” shaped with a slight suborbital shelf.

Measurements of the 60.4 mm holotype (in parentheses) and 3 paratypes, 66.6–71.4 mm, as percentage of SL: predorsal length (29.5) 28.8–30.9; preanal length (58.6) 55.6–60.6; dorsal-fin base (68.5) 70.6–71.1; anal-fin base (37.7) 32.6–34.7; pelvic-fin length (20.0) 21.5–22.4; caudal-fin length (19.7) 19.4–19.6; depth at anal-fin origin (15.6) 16.3–16.8; head length (31.6) 31.2–32.9; orbit diameter (8.5) 8.5–9.5; upper jaw length (18.4) 17.2–18.0. As percentage of head length: postorbital head length (64.7) 63.0–66.4; upper jaw length (58.1) 52.3–57.6; postorbital jaw length (20.2) 16.2–25.3; orbit diameter (27.0) 27.3–28.8.

Preserved coloration. Head and body uniformly tan; inner lining of maxilla and adjacent membranes dark brown, and a dark diagonal blotch externally on upper jaw positioned at rictus of mouth; dorsal fin with an oblong black spot between spines 3–6, encircled by narrow white border and
extending slightly onto dorsum; remainder of fin with a very narrow pale basal stripe extending length of fin and bordered, in succession, by a narrow dark stripe, another pale stripe (in the largest paratype consisting of a row of narrowly connected white spots, each of which is centred on a fin ray), bordered above by dark pigment; tips of dorsal-fin spines with swollen fleshy pads that are mostly dark (these structures pale or white in *O. alleni* and *O. seminudus*); anal fin with a narrow pale basal stripe bordered by a narrower dark stripe, remainder of fin mostly uniform brown; pectoral fins immaculate; caudal fin pale dusky, and pelvic fins dark brownish, darkest on interradial membranes. In the largest paratype the pelvic and anal fins are almost uniformly black, and the belly noticeably dark. This specimen also differs from the others in having a small pair of widely separated, pale, basicaudal spots; these spots perhaps more noticeable owing to the darker caudal fin of this specimen.

**Live coloration** (A.C. Gill, pers. comm.): body yellowish-brown and pale markings in dorsal fin blue.

**Etymology.** The specific epithet refers to the type locality. If not an Elizabeth Reef endemic, this species likely occurs only at Elizabeth and the adjacent Middleton Reef (see below).

**Distribution.** Known only from Elizabeth Reef, where collected between 0–18 m, but possibly also present at the adjacent Middleton Reef (29°30’S 159°12’E). These two coral capped, volcanic seamounts, located about 500 km off Coffs Harbour, NSW, Australia, represent the southernmost coral atolls in the world (Slater & Phipps, 1977). Francis (1993) noted that the relatively young Lord Howe Island (6.9–6.4 million years B.P.) and Elizabeth and Middleton Reefs share a large number of species and probably should be treated as a single biogeographic unit. Lord Howe Island (31°33’S 159°4’E), Elizabeth and Middleton Reefs are only three of more than 20 known volcanic peaks in the Tasman Sea (Slater & Goodwin, 1973) that form parallel north-south chains along the western margin of the Lord Howe Rise and the trough between Lord Howe Rise and Australia. Although these three peaks are the only ones presently at or above sea level, their faunas may have been derived from older, now submerged, structures.

Figs. 2C, 3E, 9, 10; Tables 1–4

**Opistognathus sp.—**Larson & Williams, 1997: 366 (listed; Darwin Harbour).

**Type material.** HOLOTYPE: NTM S.10016-003, male (52.6), Australia, Northern Territory, Cobourg Peninsula, E. side Coral Bay, 11°11’S 132°04’E, 5–6 m, Helen K. Larson and P. Homes, 18 Oct. 1981. PARATYPES: 28 specimens, 14.2–48.1 mm, all taken with the holotype. AMS I.33644-001 (4, 35.2–39.4), ANSP 167416 (4, 29.5–48.1, 1 C&S), NTM S.10016-046 (12, 14.2–47.2), USNM 320261 (4, 25.1–44.8), WAM P.30593-001 (4, 33.5–37.3).

**Diagnosis.** A species of *Opistognathus* with dorsal fin X–XI, 14 or 15 (typically XI, 14); upper jaw sexually dimorphic with flexible lamina posteriorly, end of maxilla slightly rounded (females) becoming increasingly elongate and scimitar-shaped (adult males); oblique scale rows 39–54 in longitudinal series; total gill-rakers on first arch 23–26; spinous dorsal fin with a single brownish spot, if present, between spines 2–4.

Scales absent on head, nape, above lateral line, pectoral-fin base, breast and anterior ¼ to ½ of belly. Body with about 44–54 oblique scale rows in longitudinal series. Lateral-line terminus below verticals from 2nd to 4th segmented dorsal-fin rays (total element position 13–15). Lateral line pores numerous, arranged in multiple series above and below embedded lateral-line tubes. Cephalic sensory pores numerous, completely covering most of head, including all of predorsal area except a small area immediately adjacent to dorsal-fin origin; mandibular pore positions 1–3 occupied by relatively large, single pores, 4th position with 1–3 (usually 2) pores, 5th with 3–7 pores.
in Fig. 10. Semidiagrammatic drawing showing buccal pigmentation of upper lip, consisting of a short tube with posterior rim longer, that when depressed does not reach or just reaches margin of posterior nostril; height of tube shorter than to about equal maximum diameter of posterior nostril. Dorsal fin moderately low anteriorly, with profile relatively uniform without change in fin height at junction of last spine and anterior segmented rays. Dorsal-fin spines relatively slender and slightly curved distally, with flexible tips; all segmented dorsal- and anal-fin rays branched distally or 1st anal ray unbranched. Outermost segmented pelvic-fin ray not tightly bound to adjacent ray, interradial membrane incised distally. Upper margin of opercle straight and slightly rounded posterodorsally; posterior margin of preopercle indistinct without a free margin. No papillae on inner surface of lips. Fifth cranial nerve passes under A1β section of adductor mandibulae.

Upper jaw sexually dimorphic (longest in adult males) and extending 1.1 to 2.1 eye diameters behind posterior margin of orbit; maxilla widest before end, with flexible lamina posteriorly (Fig. 2C), scimitar-shaped in adult males; supramaxilla moderately large and subterminally positioned. Jaws subequal, lower slightly included. Premaxilla with an outer row of moderately large, sharply pointed, conical teeth, those near posterior end of jaw noticeably smaller and more closely spaced; 2 or 3 irregular inner rows of much smaller conical teeth present anteriorly, with those adjacent to premaxillary symphysis slightly enlarged. Dentary with an outer row of conical teeth that are blunter anteriorly, those on posterior half of dentary largest and slightly hooked inward; 2 or 3 inner rows of slightly smaller, conical teeth anteriorly, those in innermost row canted backwards. Vomerine teeth absent. Infraorbital bones tubular, with wide openings for sensory canals (Fig. 3E); 3rd infraorbital relatively robust but without a suborbital shelf. Second pharyngobranchial rod-shaped with distal end slightly expanded.

Anterior nostril about mid-way between posterior nostril and dorsal margin of upper lip, consisting of a short tube with posterior rim longer, that when depressed does not reach or just reaches margin of posterior nostril; height of tube shorter than to about equal maximum diameter of posterior nostril. Dorsal fin moderately low anteriorly, with profile relatively uniform without change in fin height at junction of last spine and anterior segmented rays. Dorsal-fin spines relatively slender and slightly curved distally, with flexible tips; all segmented dorsal- and anal-fin rays branched distally or 1st anal ray unbranched. Outermost segmented pelvic-fin ray not tightly bound to adjacent ray, interradial membrane incised distally. Upper margin of opercle straight and slightly rounded posterodorsally; posterior margin of preopercle indistinct without a free margin. No papillae on inner surface of lips. Fifth cranial nerve passes under A1β section of adductor mandibulae.

Upper jaw sexually dimorphic (longest in adult males) and extending 1.1 to 2.1 eye diameters behind posterior margin of orbit; maxilla widest before end, with flexible lamina posteriorly (Fig. 2C), scimitar-shaped in adult males; supramaxilla moderately large and subterminally positioned. Jaws subequal, lower slightly included. Premaxilla with an outer row of moderately large, sharply pointed, conical teeth, those near posterior end of jaw noticeably smaller and more closely spaced; 2 or 3 irregular inner rows of much smaller conical teeth present anteriorly, with those adjacent to premaxillary symphysis slightly enlarged. Dentary with an outer row of conical teeth that are blunter anteriorly, those on posterior half of dentary largest and slightly hooked inward; 2 or 3 inner rows of slightly smaller, conical teeth anteriorly, those in innermost row canted backwards. Vomerine teeth absent. Infraorbital bones tubular, with wide openings for sensory canals (Fig. 3E); 3rd infraorbital relatively robust but without a suborbital shelf. Second pharyngobranchial rod-shaped with distal end slightly expanded.

Measurements of the 52.6 mm male holotype (in parentheses) and 15 paratypes, 9 ♂ ♀ 35.9–48.1 mm and 6 ♂ ♀ 35.2–47.2 mm, as percentage of SL: predorsal length (31.6) 28.9–32.0; preanal length (55.1) 52.4–56.6; dorsal-fin base (74.3) 65.0–76.1; anal-fin base (38.8) 36.3–40.8; pelvic-fin length (20.0) 20.4–22.8; caudal-fin length (21.5) 19.8–22.8; depth at anal-fin origin (15.0) 12.5–16.2; head length (32.7) 29.8–32.6; orbit diameter (8.3) 8.1–9.3; upper jaw length (25.9) 20.4–24.5 ♂ ♀ , 19.0–21.1 ♀ ♀ . As percentage of head length: postorbital head length (68.9) 65.2–68.4; upper jaw length (79.1) 65.2–78.9 ♂ ♀ , 61.6–66.5 ♀ ♀ ; postorbital jaw length (52.3) 33.9–45.3 ♂ ♀ , 29.9–35.6 ♀ ♀ ; orbit diameter (25.3) 25.7–29.9.

Preserved coloration. Head and body ground colour light tan, with darker freckling; in larger specimens branchiostegal membranes and pectoral-fin base finely peppered with melanophores; inner lining of maxilla and adjacent membranes with 2 brownish stripes (best developed in adult males) that when mouth is closed are partially visible as lateral streaks on expanded part of the upper jaw: buccal pigmentation (Fig. 10) consisting of diffuse dusky area on floor of mouth in front of esophageal opening and a pair of slightly separated dark blotches on roof of mouth behind upper pharyngeal toothplates; in some specimens, a series of small dark blotches present on sides and about 8 equally spaced blotches on dorsum along dorsal-fin base; in a few specimens first 2 blotches relatively dark and extending onto dorsal fin; dorsal and anal fins dusky with blotches and pale spots that tend to form rows; in some specimens a pair of pale basicaudal spots evident and caudal fin with several indistinct narrow dusky bands; pelvic and pectoral fins immaculate.

Etymology. The specific epithet is from the Latin verecundus (bashful or shy), in allusion to the burrow-dwelling habit.

Distribution. Known only from the type locality off Cobourg Peninsula, northern Australia, where collected in 5–6 m.

Remarks. This species is apparently most closely related to the allopatric O. solorensis Bleeker 1853, known from Indonesia, Philippines and Taiwan. Both have essentially identical upper jaw structures, dentition, fin ray and vertebral counts and buccal pigmentation. Opistognathus verecundus differs from O. solorensis in having fewer gill-rakers, with 15–17 (versus 18–20) on the lower limb and a total of 23–26 (vs. 27–33), only 44–54 oblique scale rows in longitudinal series (vs. typically 58–69), and only brown spots or markings anteriorly on the spinous dorsal fin, (vs. one or two black spots in this position).
**Opistognathus reticeps n.sp.**

Figs. 2D, 3F, 11; Tables 1–4

**Type material.** **Holotype:** NTM S.10553-004, gravid female (99.4), Australia, Northern Territory, Darwin Harbour, east arm, 12°29’S 130°53’E, 0–1 m, sta. HL 82–49, H. Larson and R. Williams, 6 Sep. 1982. **Paratypes:** 7 specimens, 19.4–117.3 mm. WAM P.24227 (113), Napier Broome Bay, Jul. 1973; NTM S.10158-003 (87.2), Van Diemen Gulf, Northern Territory Fisheries, 17 Jan. 1978, Sta. 11/9; AMS IA.7606, gravid female (117.3), Darwin, near jetty, from burrows on mud flat, M. Ward, 31 Jul. 1938; NTM S.10718-032 (63.7, C&S), Darwin Harbour, east arm, 1.5 m, H. Larson et al., 31 Dec. 1982, Sta. HL 82–91; NTM S.11242-002 (75.4), Darwin Harbour, Wood Inlet, 2 m, H. Larson and R. Williams, 16 Mar. 1984, Sta. HL 84–12; NTM S.10608-013 (19.4), N. Oxley Island, 11°00’S 132°49’E, 11–12 m, H. Larson et al., 21 Oct. 1982, Sta. HL 82–79; NTM S.13282-001 (84.2), Beagle Gulf, N. of Charles Point, 12°15.4’S 130°37.8’E, trawled in 23–29 m, R. Williams, 2 Sep. 1992, Sta. RW 92–2.

**Diagnosis.** A species of *Opistognathus* with dorsal fin XII, 15 or 16; dorsal fin with 4 dark blotches, the first 2 extending onto distal half of fin; dorsum of head reticulated; lateral-line terminus below verticals from 10th spine to 3rd segmented dorsal-fin ray.

Scales absent on head, nape, pectoral-fin base (largest specimen with a few embedded scales) and breast; 3 or 4 rows of scales present above lateral line anteriorly and 1 or 2 rows posteriorly. Body with about 56–64 oblique scale rows in longitudinal series. Lateral-line terminus below verticals from 10th spine to 3rd segmented dorsal-fin ray (total element position 10–14). Lateral-line pores relatively sparse, mostly arranged in a single series along embedded lateral-line tubes. Cephalic sensory pores relatively numerous, except pores absent on most of nape; 1st mandibular pore position bipored, all other mandibulo-preopercular pore positions occupied by multiple pores too small and numerous to count accurately; infra- and supraorbital pores also very numerous.

Anterior nostril positioned closer to posterior nostril than to margin of upper lip, and consisting of a short tube with a broad tentacle on posterior rim that when depressed extends to or nearly to posterior margin of posterior nostril; height of tentacle about 1.0–1.5 times maximum diameter of posterior nostril. Dorsal fin moderately low anteriorly, increasing in height posteriorly, with profile relatively uniform without change in height at junction of last spine and anterior segmented rays. Dorsal-fin spines relatively slender and only slightly curved, with flexible tips; skin covering tips of dorsal-fin spines somewhat rugose but without fleshy tabs; all segmented dorsal- and anal-fin rays branched distally, except first 1 or 2 anal rays usually unbranched. Outermost segmented dorsal- and anal-fin rays not tightly bound to adjacent ray, interradial membrane incised distally. Upper margin of opercle straight and slightly rounded posterodorsally; posterior margin of preopercle distinct, with a free margin. No papillae on inner surface of lips. Fifth cranial nerve passes over A1β section of adductor mandibulae.

Upper jaw not sexually dimorphic, extending about 0.7–1.0 eye diameters behind posterior margin of orbit; maxilla widest at end and rounded, without flexible lamina posteriorly (Fig. 2D); supramaxilla present, relatively small and terminally positioned. Jaws subequal, lower slightly included. Both jaws with an outer row of enlarged conical teeth that are relatively straight and slant forward, especially anteriorly; 1 or 2 irregular rows of much smaller inner teeth present anteriorly, those adjacent to premaxillary symphysis slightly enlarged and canted posteriorly. Vomerine teeth absent. Infraorbital bones relatively slender and tubular (Fig. 3F); 3rd infraorbital with a slight suborbital shelf. Second pharyngobranchial rod-shaped with distal end slightly expanded.

Measurements of the 99.4 mm holotype (in parentheses) and 5 paratypes, 75–117 mm, as percentage of SL: predorsal length (39.0) 34.6–40.0; preanal length (63.9) 56.9–67.0; dorsal-fin base (62.6) 60.1–69.1; anal-fin base (26.6) 25.4–30.1; pelvic-fin length (22.6) 20.4–25.3; caudal-fin length...
Preserved coloration. Dorsum of head, snout, upper part of opercle, and nape reticulated with irregular pale markings or spots, remainder of head and body mostly pale to light dusky, except blotches in dorsal fin usually continue across the body as faint bands (best developed in smaller specimens), and a similar basicaudal band may be present on caudal peduncle; dorsal fin with four dark blotches that extend slightly onto dorsum; interradial membranes immediately adjacent to blotches lighter than rest of fin and almost clear in the smaller paratypes; anterior two blotches extending to or almost to distal margin of fin, others becoming progressively smaller in height; 1st blotch extending to or almost to distal margin of fin, others almost clear in the smaller paratypes; anterior two blotches extending to or almost to distal margin of fin, others becoming progressively smaller in height; 1st blotch positioned between spines 3–6, 2nd between spines 9–12, 3rd between rays 3–6 and 4th between rays 10–14; dorsal and anal fins with narrow dark margins, widest posteriorly; remainder of anal fin pale or with one or two dark spots, slightly smaller than pupil diameter, in basal half of fin aligned with blotches in dorsal fin; caudal fin pale except for narrow dark margin; pelvic fins immaculate and pectoral fins faintly speckled.

Etymology. The specific epithet is from the Latin rete (net) and ceps (head), in reference to the reticulated dorsum of the head that is a distinguishing feature of this species. The name should be treated as a noun in apposition.

Distribution. Known only from northern Australia.

Remarks. Only Opistognathus reticulatus and four other species of jawfishes have 12 dorsal-fin spines, and all have different colour patterns (see following identification key). Opistognathus reticulatus apparently is much smaller (largest individual, a 117 mm SL gravid female) than the other four, all of which attain at least 200 mm. The largest specimens examined (mm SL) of the others are: O. inornatus (409); O. papuensis (339); O. reticulatus (368); O. latitabundus (216).

Key to Australian jawfishes

1. First 5–9 dorsal-fin spines transversely forked distally (posteriorly spines successively less deeply and more narrowly forked); skin covering spinous dorsal fin forming a broad dorsal hood to accommodate transversely forked spines; segmented anal-fin rays 10 or 11 ................................................................................................................................. 2
   — Anterior dorsal-fin spines not transversely forked; skin covering spinous dorsal fin not forming a broad dorsal hood; segmented anal-fin rays 10–19 ................................................................................................................................................................. 3

2. Posterior edge of opercle and adjacent branchiostegal membranes dark and conspicuous; dorsal, anal, and caudal fins with two, broad dark stripes or bands (Japan, Indonesia, Great Barrier Reef, and New Caledonia) .......................................................................................................................... Stalix histrio Jordan & Snyder, 1902
   — Posterior edge of opercle and adjacent branchiostegal membranes not conspicuously pigmented; dorsal, anal and caudal fins without dark stripes or bands (western Australia) .......................................................................................... Stalix flavida Smith-Vaniz, 1989

Status of Tandya Whitley

Whitley (1930) established the genus Tandya (type by original designation, Opistognathus maculatus Alleyne & Macleay, 1877 = O. papuensis Bleeker, 1868) for Australian jawfishes that have 12 dorsal-fin spines and upper jaws with a truncate maxilla extending posterior to a vertical from the posterior margin of the orbit. He contrasted his new genus only with Gnathyphops Gill (type species Opistognathus maxillosus Poey, 1860), which was erroneously reported to have 8 (actually 11) dorsal-fin spines. Smith-Vaniz (1997) redescribed O. maxillosus, recognizing Gnathyphops as a junior synonym of Opistognathus Cuvier. Inexplicably, both Whitley (1930) and McKay (1969) assigned Opistognathus darwiniensis Macleay, 1878 to Tandya although it has only 11 dorsal-fin spines. Three other jawfishes with 12 dorsal-fin spines that have sometimes been referred to Tandya are Opistognathus inornatus Ramsay & Ogilby, 1887, Tandya latitabunda Whitley, 1937 and Tandya reticulata McKay, 1969. Opistognathus inornatus differs from the allopatic O. papuensis only in colour pattern and its taxonomic rank is subjective.

Species in the following key that have 12 (rarely 13) dorsal-fin spines also have more precaudal vertebra than other opistognathids (12 or 13 versus 10 or 11), except O. darwiniensis with typically 12+19 vertebrae and 10 or 11 (usually 11) dorsal-fin spines. Opistognathus darwiniensis is also exceptional in having a second, irregularly developed, tubed lateral line (often with one or more branches on belly) present along the lower sides near the anal-fin origin. Numbers of dorsal-fin spines and precaudal vertebrae vary widely among percoids, and in the absence of a reasonably supported sister-group hypothesis for the Opistognathidae (see discussion in Gill & Mooi, 1993), polarity of such meristic characters is equivocal. High numbers of spines and precaudal vertebrae could have evolved in the ancestor of the Opistognathidae; that possibility combined with the lack of character state concordance in such meristic characters is equivocal.
3 Dorsal-fin spines 10 or 11 ................................................................. 4
   — Dorsal-fin spines 12 or 13 (rarely 13) ........................................... 13

4 Body with 2 separate lateral lines, the ventral one irregularly
developed along lower side in region of anal-fin origin, often with
one or more branches on belly; head covered with close-set, tiny,
brown spots and pelvic fins usually strongly barred; precaudal
vertebrae 12 or 13 (northwestern Australia) .................... Opistognathus darwiniensis Macleay, 1878
   — Body with a single, dorsally positioned lateral line; colour pattern
not as above; precaudal vertebrae 10 or 11 ........................................ 5

5 Segmented dorsal- and anal-fin rays 11–13 and 10–12, respectively .......... 6
   — Segmented dorsal- and anal-fin rays 14–20 and 13–19, respectively .......... 8

6 Opercle with a conspicuous dark blotch; scales on belly minute
and distinctly embedded; body with about 80–99 oblique scales
in longitudinal series; vomerine teeth 1–3; upper gill-rakers 14–
17 (eastern Australia) ........................................ Opistognathus eximus (Ogilby, 1908)
   — Opercle without a dark blotch; scales on belly, if present, small to
moderate and not distinctly embedded; body with about 41–62
oblique scales in longitudinal series; vomerine teeth absent; upper
gill-rakers 9–12 ................................................................. 7

7 Spinous dorsal without an ocellus; soft dorsal and anal fins mostly
dark with a narrow pale basal stripe; no dark chin bar; outer
premaxillary teeth relatively straight and with distinctly blunt tips;
nape at least partially scaled (gulfs of Thailand and Carpentaria)
................................................................................ Opistognathus macrolepis Peters, 1866
   — Spinous dorsal fin with a prominent ocellus; coloration of soft
dorsal and anal fins not as above; dark chin bar present; outer
premaxillary teeth variously curved and with pointed tips; nape
usually naked (western Pacific, including Great Barrier Reef, Fiji
and Samoa islands) ........................................................ Opistognathus sp. “chinstrap jawfish”

8 Floor of mouth between dentaries and “tongue” dark brown; dorsal
fin X, 16–18, rarely 16; body with about 80–99 oblique scale
rows in longitudinal series (eastern Australia) .......... Opistognathus jacksoniensis Macleay, 1881
   — Floor of mouth between dentaries and “tongue” pale; number of
dorsal-fin spines and rays not in above combination; body with
about 21–54 oblique scales in longitudinal series .......................... 9

9 Posterior end of upper jaw produced as a thin flexible lamina in
adults (beginning as a slight posteroventral projection in small
juveniles); in at least adult males upper jaw extends to or beyond
posterior margin of preopercle and appears somewhat scimitar-
shaped; roof of mouth behind upper pharyngeal toothplates with
a pair of slightly separated dark blotches; total dorsal-fin elements
25 (rarely 26); lateral-line terminus below verticals from 2nd to
4th segmented dorsal-fin rays (northern Australia) ............ Opistognathus verecundus n.sp.
   — Posterior end of upper jaw rigid in adults, without a flexible lamina;
upper jaw not extending to posterior margin of preopercle, truncate
or moderately rounded but never scimitar-shaped; roof of mouth
behind upper pharyngeal toothplates immaculate; total dorsal-fin
elements 25–30; lateral-line terminus below verticals from 4th to
17th segmented dorsal-fin rays ........................................... 10

10 Segmented dorsal- and anal-fin rays 14–16 and 14 or 15,
respectively; body naked anterior to a vertical between ultimate
spine and 2nd segmented dorsal-fin rays; caudal vertebrae 18
(Great Barrier Reef) ....................................................... Opistognathus seminudus n.sp.

<tbody>
<tr>
<td>11</td>
<td>Body naked anterior to a vertical line from 6th to 9th segmented dorsal-fin rays; lateral line terminus below verticals between 13th and 17th segmented dorsal-fin rays; body with 21–31 oblique scale rows (western Australia). <strong>Opistognathus alleni</strong> n.sp.</td>
</tr>
<tr>
<td>12</td>
<td>Spinous dorsal fin with an oblong black spot (encircled by narrow white border) between spines 3–6 that extends slightly onto dorsum; dorsal-fin spines 11; vomerine teeth 2 or 3; sides of body uniformly pigmented (Elizabeth Reef). <strong>Opistognathus elizabethensis</strong> n.sp.</td>
</tr>
<tr>
<td>13</td>
<td>Dorsal fin with 4 or 5 large dark blotches that extend onto dorsum; lateral line terminus below verticals between 10th spine and 5th segmented dorsal-fin ray; 56–80 oblique scale rows in longitudinal series. <strong>Opistognathus reticeps</strong> n.sp.</td>
</tr>
<tr>
<td>14</td>
<td>Dorsal fin with 4 dark blotches, first blotch extending onto distal half of fin; inner surface of mouth, and skin connecting dentary and maxilla pale; dorsum of head reticulated; total gill-rakers on first arch 26–29; vertebrae 12+19 (northern Australia). <strong>Opistognathus latitabundus</strong> (Whitley, 1937)</td>
</tr>
<tr>
<td>15</td>
<td>Body with pale reticulate network enclosing irregular tan blotches, each of which has one to several small, dark-brown spots; pectoral-fin base (laterally and mesially) with a conspicuous dark spot about half diameter of eye; pelvic and anal fins white; vertebrae 13+18 (northwestern Australia). <strong>Opistognathus reticulatus</strong> (McKay, 1969)</td>
</tr>
<tr>
<td>16</td>
<td>Body with numerous small spots, especially on dorsum of head; pectoral fin with several to many tiny dark spots; background coloration of body pale (in life, light tan), darker dorsally (Waigeo and Queensland to Darwin, Australia). <strong>Opistognathus papuensis</strong> Bleeker, 1868</td>

ACKNOWLEDGMENTS I thank the following for loans of specimens: G.R. Allen (WAM), W.N. Eschmeyer (CAS), A.C. Gill (BMNH), R.D. Mooi (MPM), J.C. Paxton (AMS), J.E. Randall (BPBM), H.K. Larson (NTM), and V.G. Springer and J.T. Williams (USNM). Colour photographs of jawfishes were generously provided by G.R. Allen, R.D. Mooi, and P.C. Heemstra, South African Institute of Aquatic Biology (formerly RUSI). I also thank R.D. Mooi for discussion of problems involving opistognathid intrafamilial relationships. The manuscript benefited from comments provided by Martin Gomon and an anonymous reviewer.
